

eQTL mapping

# Our plans for today

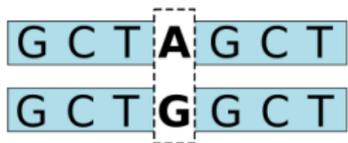

Learn the basics of eQTL analyses:

- ▶ Understand what an eQTL analysis is
- ▶ Revise some basics in genetics
- ▶ Understand how an eQTL analysis works
  - ▶ Step-by-step understand which data is needed
  - ▶ Understand what the data is means
  - ▶ Look at basic quality measures
- ▶ Look at a locus in more detail

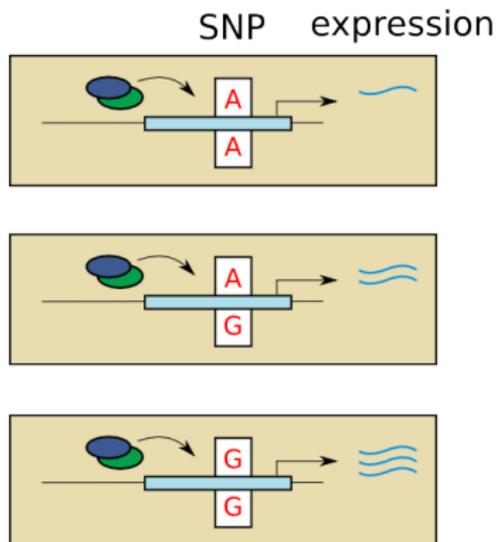

## eQTL analysis

- ▶ mRNA levels are measured simultaneously on thousands of genes using expression arrays or RNAseq
- ▶ Hundreds of thousands of SNPs are available through genotyping arrays or genome sequencing
- ▶ The aim: Identify association of SNPs with molecular traits
- ▶ Advantage of molecular traits:
  - ▶ Quantifiable
  - ▶ Objectively measured
- ▶ Associated SNPs can then be overlapped with genome annotation.

# eQTL analysis

Genotyping

## Differences to other association studies

- ▶ Gene expression is a continuous value, not yes/no (“Quantitative trait”)
- ▶ Quantitative trait locus: a chromosomal region that affects the levels of a heritable quantitative trait.
- ▶ Gene expression and mRNA abundance of a given gene—is also heritable.
- ▶ eQTL (expression Quantitative Trait Locus) is the regulatory region for an expression trait.
- ▶ eQTL mapping is QTL mapping with an expression trait used as the phenotype.

# Which ingredients are needed?

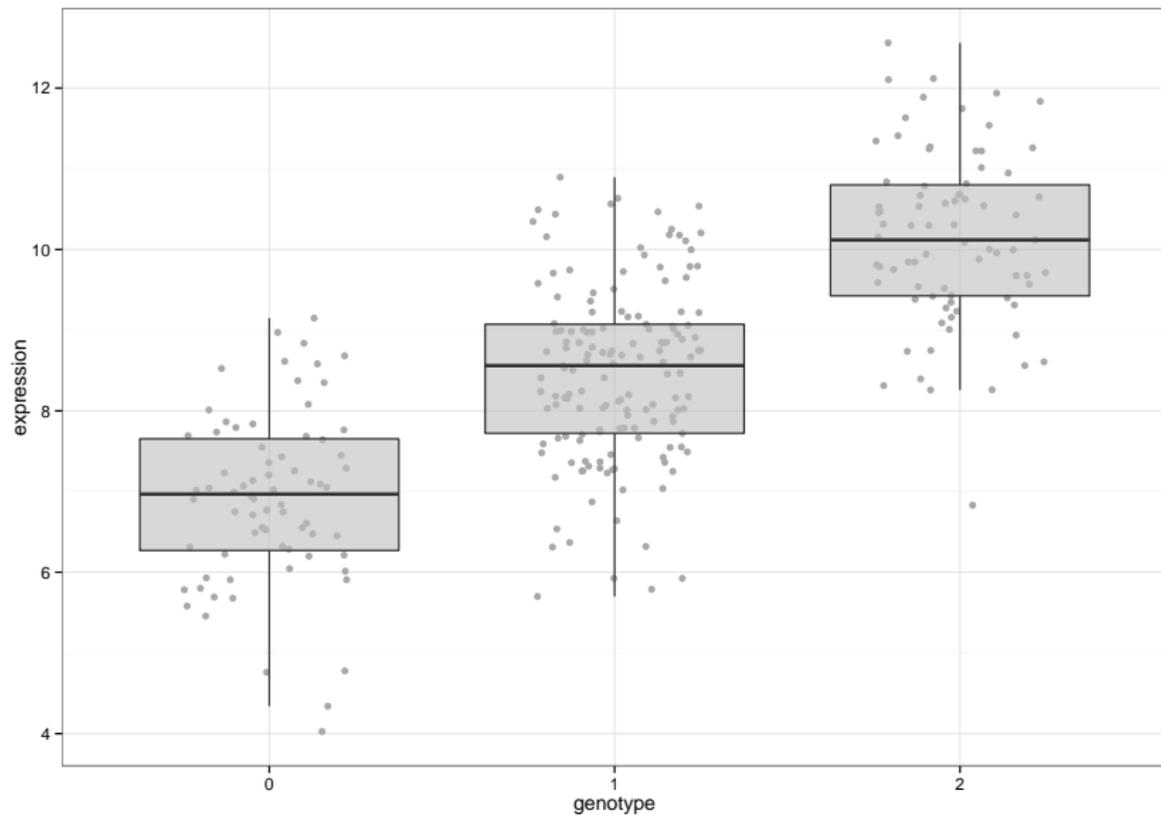

From each sample:

- ▶ Genotype data
- ▶ Gene expression data
- ▶ Covariates
  - ▶ Sex
  - ▶ Age
  - ▶ Smoking habits
  - ▶ Environmental effect sources
  - ▶ ...

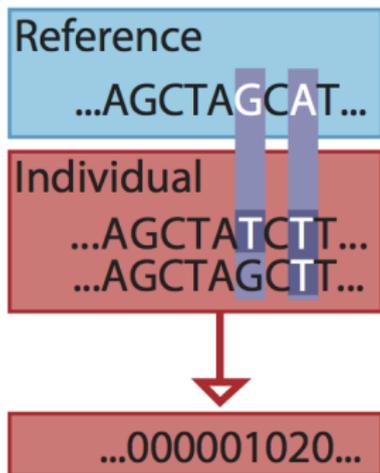

## How does it work?

- ▶ Take expression levels of a gene
- ▶ Take genotype alleles at a certain position
- ▶ Measure correlation
- ▶ Estimate how trustworthy compared to other random SNP (= p-value)

# Gene expression

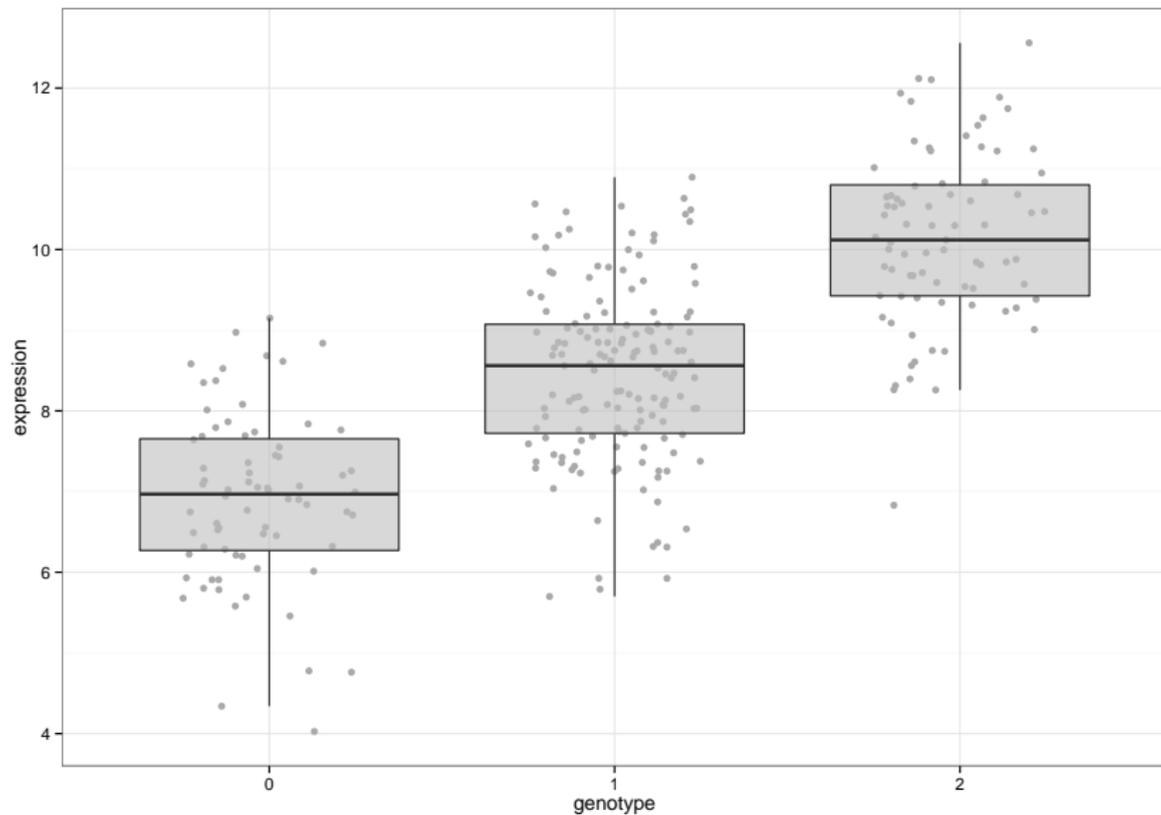

## Genotype coding of individuals

Spotting the differences:

- ▶ Individual has two SNPs
- ▶ In eQTL analyses SNPs can only have two alleles: The reference and the alternative.
- ▶ Each individual can have 0, 1 or 2 times the alternative allele.

# Gene expression

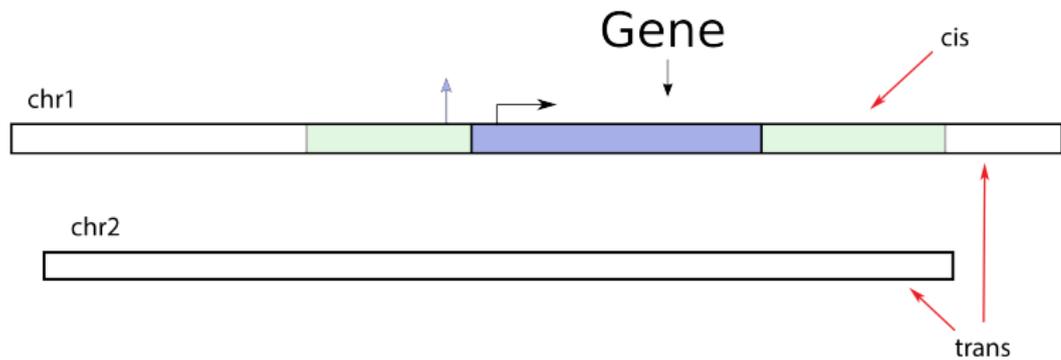

# How do we select what to test?

- ▶ All genes are tested
- ▶ Genotype information is present for many locations (“SNP”) within and between genes
- ▶ For each gene select a subset of those SNPs and test for association
  - ▶ Select SNPs close to a gene: cis
  - ▶ Select SNPs further away from the gene: trans
- ▶ Why not use the entire genome?
  - ▶ Multiple testing burden would hide many cis-associations
  - ▶ Differentiation between cis and trans effects

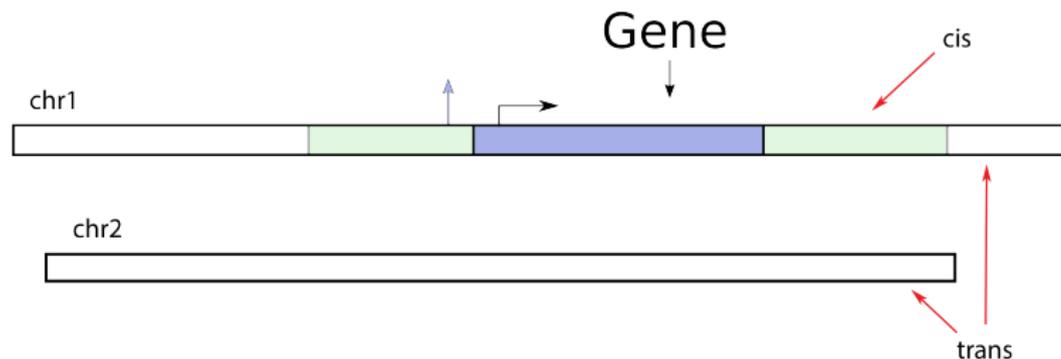

# What is a cis / trans effect

- ▶ cis-effect:
  - ▶ The genetic variant in an individual (SNV) directly affects the expression of its associated gene
- ▶ trans-effect:
  - ▶ Gene expression is affected through possibly complex effects in which the genetic variant is involved
- ▶ How can we distinguish those?
  - ▶ Genomic linear distance of the tested SNP from the tested gene
    - ▶ Low distance: More likely cis-effect
    - ▶ High distance: More likely trans-effect

# cis- and trans-eQTL testing

## cis- and trans-eQTL testing

For each gene:

- ▶ cis: test all SNPs within 500kb around the gene (100s)
- ▶ trans: test all other SNPs in the genome (millions – 100s of millions)

# Different models and programs

## Linear (mixed) models

- ▶ MatrixEQTL (R package), FastQTL, LIMIX, PLINK, ...

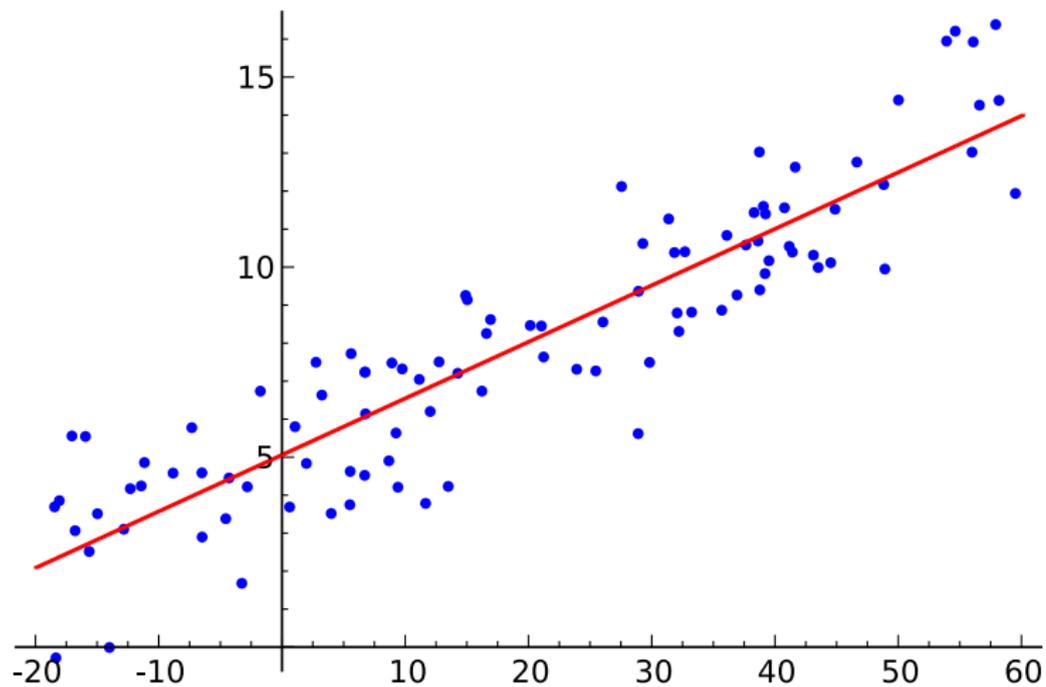

## Random Forests

- ▶ LIMIX, ...

## Bayesian approach

- ▶ GOAL (R package), ...

## Linear regression

# Linear regression in eQTLs
